Abstract: **PURPOSE:** To prevent the incidence of the irregularly reflected light from a material to be worked to a laser oscillator by providing a mechanism for condensing once the laser beam drawn out from the oscillator and passing the same through small hole then running in parallel again the same between a taking-out port and a condenser lens.
CONSTITUTION: The laser beam 7 from a taking-out port 5 of a laser oscillator 1 is condensed by the 1st lens 13 and is passed through a pinhole 14a of a shielding plate 14 provided in the position at the focal length thereof, then the light is returned to the laser beam 7 running in parallel in the same direction by the 2nd lens 15. The beam 7 is radiated, via a reflecting mirror 8 and a condenser lens 9, to a material 11 to be worked. A part of the beam 7 reflects irregularly on melting of the material 11 and goes backward into an optical head H2 via a nozzle 10, but can hardly pass the pinhole 14a of the plate 14 so that the retrogression into the oscillator 1 is prevented.
